Week-6

5/11/26 CST1510 Pandas

- groupby() splits the rows into groups
- agg() is used to do more than one summary at once eg, mean, max etc. You have to create a list to display them. so ["mean", "max"]
- instead of doing groupby(...) & .size() we can do print(server["..."].value_counts())
- we use sort_values("percent") to sort in ascending order in percent colm
- .apply() loops the function so its just like for loop.
- Lambda can have only one expression we can also use lambda to sort_values("hostname", key = lambda col: col.str.lower())

which basically sorts the hostname column in ~~ascen~~ alphabetically order ignoring the uppercase & lowercase. using .lower() we notice e

we make everything lower case.

★ To save a new file we use
df.to_csv("...csv", index=False)

↓ This adds the new (Cstates, percent) info along with existing info into a new file
(label, value, limit)

This means it won't be indexed
